

Grower guide to assessing legume nodulation

THE UNIVERSITY
of ADELAIDE

Upper Eyre Peninsula

(Lupin, Field pea / Vetch, Medic, Chickpea)

- Was your legume inoculation successful? If you didn't inoculate, should you do so in future?
- You can check to see if this year's legume nodulation is adequate.
- See short, instructional videos at: www.ua.edu.au/legume-inoculation

METHOD

1. In late winter or early spring (or about 10 – 12 weeks after sowing), collect about 30 plants, 10 at each of 3 sample spots (see sample pattern diagram), putting each sample of 10 in a separate bucket.
2. Carefully wash off the soil in a bucket of water and rinse roots once or twice to remove remaining soil. (Soak for up to 30 min for heavy soils).
3. Score each plant for adequate / poor nodulation (refer to photos of adequate and poor nodulation and desirable numbers of nodules per plant, see over). Sort plants into two groups: adequately and poorly nodulated, work out the % plants adequately nodulated and then the average score for the three sampling locations. For easier assessment, float the roots in water on a white background.

Equipment needed

Buckets, spade, water

Sampling pattern (sample at "x")

OVERALL AVERAGE NODULATION SCORE:

Overall success rating	
Adequate	70% or more of plants rated adequate
Borderline	50 – 70% of plants rated adequate
Poor	Less than 50% of plants rated adequate
None	No nodules present (= no nitrogen fixation)

NOTE: Plants scored as *Adequate* should have most nodules with a red/pink colour inside (actively fixing nitrogen).

LUPIN

Adequate

Photo: Ross Ballard SARDI

Nodules right around the crown & on laterals;
Plant on R: nodules have been sliced open to reveal pink interior (arrowed)

Poor

Few nodules (arrowed)

Note: Normal lupin roots can have a pink interior that is unrelated to nodulation

PEA / VETCH

Adequate

Photo: Liz Farquharson SARDI

50 to 100 nodules
(20 nodules per plant on lighter soils)

Poor

Less than 20 nodules (red-brown earth)

MEDIC

Adequate

5 to 10 nodules per plant (8 in this case)

Poor

(3 nodules)

CHICKPEA

Adequate

Photo: Andrew Heath

Adequate: 10 to 30 nodules;
note multi-lobed nodules around crown

Poor

What if the nodulation score is poor?

1. Sample elsewhere in the paddock to see if it is a localised problem or not.
2. Answer the questions in the next column.
3. Look for further information on troubleshooting:
e.g. the “Nodulation Assessment Guide” or “Inoculating Legumes: A practical Guide”, via

www.ua.edu.au/legume-inoculation

(Internet search: legume growers resources).

Inoculant groups:

Use correct inoculant type

<i>Lupin</i>	<i>Group G only</i>
<i>Pea / Vetch</i>	<i>Group E or F</i>
<i>Strand Medic</i>	<i>Group AL only</i>
<i>Other Medics</i>	<i>Group AM only</i>
<i>Chickpea</i>	<i>Group N only</i>

Selected troubleshooting questions for poor nodulation of freshly inoculated legumes:

Incorrect inoculant group used?

Inoculant mixed with poor quality water (eg saline or chlorinated)?

Inoculant combined with potentially toxic pesticides, trace elements or organic amendments?

Inoculant combined with fertilizer?

Dry sowing into paddock with no background of correct rhizobia?

Sowing into extremely acidic soil (pH less than 5 in CaCl₂; except for lupin inoculant)?

Was soil waterlogged for an extended period during the growing season?

Herbicide damage from previous or current crop? (NOTE: SU herbicides in alkaline soils can dramatically inhibit nodulation of legumes in following years).

NOTE: If it is the first time to grow this legume crop in the paddock, the rate of inoculant application can be doubled.

This guide is based on the work of Janine Sounness, formerly pulse agronomist with Agriculture Victoria, Horsham
